I. INTRODUCTION

Data mining is the process of nontrivial extraction of implicit, previously unknown, and potentially useful information from data that can help the businesses to make proactive and knowledge driven decisions. It uses machine learning, statistical and visualization techniques to discover and present knowledge that previously went unnoticed. Opinion mining is an important sub discipline within data mining and natural language processing (NLP), which automatically extracts, classifies, and understands the opinion generated by various users. These techniques also help to enhance the value of existing information resources that can be integrated with new products and systems as they are brought on-line. The growth of tremendous amount of online information from various forums has made very difficult for the customers to acquire information that are useful to them. This has motivated on the detection of hotspot forums [5] where useful information are quickly made available for those customers which might make them benefit in decision making process. In topic-based classification, topic related words are important.

Efficient statistical and machine learning techniques can be applied to process the enormous amount of online data. An emergent technique called Emotional polarity computation also known as sentiment analysis [6] can also be performed during online text mining. However, in opinion classification, topic-related words are not very important. But, opinion words that indicate positive or negative opinions are important, e.g., great, excellent, amazing, horrible, bad, worst, etc. Most of the methodologies for opinion mining apply some forms of machine learning techniques for classification. Customizedalgorithms specifically for opinion classification have also been developed, which exploit opinion words and phrases together with some scoring functions. In this paper we detect the hotspot forums by computing text sentiment analysis. This method quantifies the user attention on any forum with which hotspot forums can be identified. The proposed work is then integrated with K-means clustering and Support Vector Machine with Particle Swarm Optimization (SVM-PSO) algorithm. It optimally groups the forums into two clusters, forming hotspot forums and nonhotspot forums within each time window. The rest of the paper is structured as follows: Section 2 discusses related works that describes various existing semantic orientationbased sentiment classification approaches. The proposed Support Vector Machine along with Particle Swarm Optimization (SVM-PSO) algorithm is discussed in Section 3. The experimental results were discussed in Section 4. Finally Section 5 concludes the paper.

II. RELATED WORKS

This section focuses various streams of related work such as analysis of review mining, sentiment classification, machine learning techniques for predicting hotspots. 2.1. Analysis of Review Mining Mining of online reviews has become a flourishing frontier in today's environment as it can provide a solid basis for predicting future events. For example Zhou et al in 2005 [1] has stated that online reviews became more useful and influence the sales as it provides important information about the product to Page |1

potential consumers. A multi-knowledge based approach is proposed where WordNet, statistical analysis and movie knowledge are integrated. The experimental results have shown the effectiveness of the approach in movie review mining and summarizing. Hu et al [4], in his work has proposed a method in which a generated and semantic orientation labelled list containing only adjectives are used for analysing. Finally it is observed that machine learning is used to depict the interacting structure of reviews.

2.2. Sentiment Classification The documents available on the web can be classified based on various metrics including topics, authors, structures, and so forth. Classification based on sentiments has become a new frontier to text mining community. The task of sentiment classification is to determine the semantic orientations of words, sentences or documents. Most of the early work on this topic used words as the processing unit.

An automatic sentiment classification at document level has been done by Pang and Vaithyanathan[7] in which several machine learning approaches are used with common text features to classify movie reviews from IMDB. It has been pointed out that direct marketing is a promotion process which has motivated customers to place orders through various channels [6,9].

In order to work for this, one is needed to have an accurate customer segmentation based on a good understanding of the customers, so that relevant product information can be delivered to different customer segments. Thelwall et al. [11] has stated that analysing Twitter has given insights into why certain events resonate with the people. It is found that the customers, who are used to having only a limited range of product choices due to physical and/or time constraints, are now facing the problem of information overload. An effective way of increasing customer satisfaction and consequently customer loyalty has been done that has helped the customers identify products according to their interests.

This again has called for the provision of personalized product recommendations [8, 9]. Hofmann and Puzicha in their work have used the Latent Class Model (LCM) to circumvent the aforementioned problems. Paltoglou and Thelwall [2,10] have explored in their work that incorporating sentiment information into Vector Space Model (VSM) values using supervised methods was helpful for sentiment analysis.

2.3. Machine Learning Techniques for Predicting Hot Spots For predicting online hotspot forums two machine learning techniques [5] have been proposed by Nan Li and Dash. It includes K-means and SVM. Unlike other learning methods, SVM's performance is related not to the number of features in the system, but to the margin with which it separates the data. SVM [3] achieves a clustering result by exactly classifying each forum as either hotspot forum or non-hotspot forum.

III. METHODOLOGY

The proposed work helps in detecting hotspot forums and achieves highly consistent results by applying an efficient optimization algorithm with SVM-PSO. Figure 1 depicts the conceptual diagram of proposed approach.

Figure 1. Conceptual diagram of the proposed approach

3.1. Pre processing

The data set used in our experimental research is acquired from forums.digitalpoint.com and after data cleaning they are formatted to 37 different forums and 1616 threads. The data collection is initiated by crawling the forum names of first 50 forums. The parsed forum names are then stored in a table. Then all the thread posts and the reply posts contained in the corresponding web pages are parsed and they are stored separately in a table. After crawling process is achieved data cleaning is done where noise data and irrelevant data are manually removed. Noise data include forums with picture postings that are not clearly shown online. Irrelevant data are from forums where the posting contents are not related to the forum threads at all. The threads that have no replies and the forums that have no

threads across the time window are also removed. The data before cleaning and after cleaning are listed in Table 1. Finally after cleaning, 37 forums are narrowed down within the time span from January to October and each time window is of a month length over the year 2011.

Table 1. Data view before creating and after greating	Table 1.	. Data	view	before	cleaning	and	after	cleaning
---	----------	--------	------	--------	----------	-----	-------	----------

	Before cleaning	After cleaning	
Time period	2007 Jan to 2011 Oct	2011 Jan to 2011 Oct	
Number of forums	50	37	
Number of threads	2430	1616	
Number of replies	39239	19370	

3.2. Feature Extraction

The pre-processing work is followed by feature extraction process. For each forum five features are extracted across each time window such as the number of threads, the average number of replies of threads, the average sentiment value of threads, the fraction of positive threads among all the threads and the fraction of negative threads among all the threads. Sentiment value for each thread can be calculated by computing text sentiment.

3.3. Sentiment Computation on Forum Text Feature extraction includes text sentiment analysis which aims at calculating an integer value for each piece of text. It is a semantic orientation based approach where the sentiment values for all keywords are added to achieve the sentiment value for the whole article. The replies of thread are decomposed into a set of keywords. For each keyword a sentiment value is assigned.

The sum of the sentiment values for all the keywords will give the sentiment value for the thread. Suppose for a thread t, its replies are decomposed into a set of key words. For each key word wi (i=1, 2,...,n) let the sentiment value be si. Then the sentiment value St of the thread t can be calculated as using Eq.(1) Calculation of sentiment value is based on SentiStrength. SentiStrength is an algorithm for text sentiment analysis that helps in estimating the sentiment values for texts.

3.4. Forum Clustering Using K-means After the features are extracted clustering can be carried out using K-means algorithm in Rapid miner tool. Each forum may be represented as a data point in a vector space.

During the feature extraction process a vector is used to represent the emotional polarity of any forum and it is composed of five elements: the number of threads, the average number of replies of threads, the average sentiment value of threads, the fraction of positive threads among all the threads and the fraction of negative threads among all the threads. These datasets are given as the input to the k means clustering where a clustered view of all the forums is obtained. The hotspot and non hotspot forums being obtained, within each time window are those closest to the theoretical centres of clusters.

3.5. Forum Classification using SVM-PSO Classification can be carried out using Support Vector Machine with Particle Swarm Optimization (SVM-PSO) algorithm. PSO is a computational method that optimizes a problem by iteratively trying to improve a candidate solution with regard to a given measure of quality. The proposed work PSO aims at optimizing the accuracy of SVM classifier. The standard SVM-PSO takes a set of input data and it optimally predicts, for each given input, which of two possible classes comprises the input. SVM-PSO is employed to realize hotspot forecasting. In order to forecast the hotspot forums within the current time window the clustering result obtained by K-means approach from the previous time window is used. SVM-PSO performs forum classification iteratively and tries to find the optimized solution. For each SVM-PSO, the input is a forum's representation vector and the optimized output is achieved by classifying each forum as either hotspot forum or non-hotspot

The accuracy in predicting hotspot forums is improved with the proposed model and the consistency of the model is validated for its performance.

IV. EXPERIMENTAL RESULT

The data that we have collected for our empirical studies are from forums.digital point.com. A list of posts in the form of threads and replies has been crawled from January 2007 to October 2011. The data view before and after cleaning is depicted in Table1. After cleaning the data are narrowed to 37 forums from January 2011 to October 2011 and then the features are extracted that includes computing sentiment values for threads. The feature extraction is then followed by K-means clustering and classification using Support Vector Machine with Particle Swarm Optimization (SVM-PSO) among the 37 leaf forums for each time window in 2011. Clustering and classification is done using Rapid miner tool.

The results that have been obtained using Support Vector Machine with Particle Swarm Optimization (SVM-PSO) present a noticeable consistency with the results achieved by K-means clustering. The forums that are most popular among the users based on average number of threads include 'Search Marketing, Publisher Network, adcenter, General Marketing', etc. The forums that are popular based on average number of replies include 'Affiliate Programs-Google, Affiliate Network, Payments, Google-Google+',

The classification model for forums etc from forums.digitalpoint.com is shown in Figure 2.

Figure 2. Classification model using SVM-PSO

The forums that are mostly identified as hotspots by both Kmeans clustering and Support Vector Machine with Particle Swarm Optimization (SVM-PSO) over the time window from JAN 2011 to OCT 2011 are shown in Table 3.

Table 3. Forums mostly identified as hot spot by K-means and SVM-PSO

Forum ID	Forum name
11	Affiliate Network
44	Google
10	Google+
6	Reporting & Stats
49	ClickBank

4.1. Performance

Evaluation Affiliate Network Google Google+ Reporting & Stats ClickBank The consistency between K-means and Support Vector Machine along with Particle Swarm Optimization (SVM-PSO) algorithms is validated using five metrics. They are accuracy, sensitivity, specificity, positive predictive value and negative predictive value. A set of these five metrics are applied for each time window which are defined as follows. Accuracy = TP + TN / (TP + TN + TN)FP + FN) (2) Sensitivity = TP / (TP + FN) Specificity = TN/(TN + FP) PPV NPV = TP / (TP + FP) = TN / (TN + FN)(3) (4) (5) (6) Where, TP denotes the number of forums that are estimated as hotspots by both K-means and SVM-PSO.

TN denotes the number of forums that are estimated as non hotspots by both K means and SVM-PSO. FP denotes the number of forums that are estimated as hotspots by SVM PSO whereas non-hotspots by K-means. FN denotes the number of forums that are estimated as non-hotspots by SVM-PSO whereas hotspots by K-means.

Using formulae (1)-(5), the performance is evaluated for each time window. The time windows are those that are used in SVM-PSO classification process. Table 4 suggests that the proposed classification algorithm gives an optimized accuracy result than that of the other classification algorithms. Similarly the performance can be evaluated using other four metrics and the results can be compared. Figure.3 shows a graphical view of the accuracy result.

Time	Accuracy (%)					
window	Naïve Bayes	Decision Tree	SVM	SVM-PSO		
2	64	80	84	96

Figure 3. Accuracy comparison while using SVM-PSO and other algorithms

V. CONCLUSION

This paper proposes a new approach for predicting hotspot forums. In this approach emotional polarity of the text is obtained by computing a value for each piece of text. After calculating the sentiment values the method is then integrated with K-means clustering and SVM-PSO classification algorithms for forums cluster analysis. Computation indicates both K-means and SVM-PSO produce consistent grouping results. Thus the efficient detection of hotspot forums based on sentiment analysis might make internet social network members benefit in the decision making process.
